

Package ‘ggpointdensity’

November 18, 2025

Type Package

Title A Cross Between a 2D Density Plot and a Scatter Plot

Version 0.2.1

Description A cross between a 2D density plot and a scatter plot, implemented as a 'ggplot2' geom. Points in the scatter plot are colored by the number of neighboring points. This is useful to visualize the 2D-distribution of points in case of overplotting.

count_neighbors	2
geom_pointdensity	2
stat_pointdensity	6

Index	11
--------------	-----------

count_neighbors	<i>Count Neighbors within a Radius</i>
-----------------	--

Description

This function counts the number of neighboring points within a specified radius for each point in a given set of coordinates using a C implementation.

Usage

```
count_neighbors(x, y, r2, xy)
```

Arguments

x	A numeric vector of x-coordinates of the points.
y	A numeric vector of y-coordinates of the points.
r2	A numeric value representing the squared radius within which to search for neighboring points.
xy	A numeric value representing the aspect ratio (usually the ratio of the y-scale to the x-scale).

Value

A numeric vector where each element represents the count of neighboring points within the specified radius for each point.

geom_pointdensity	<i>A cross between a scatter plot and a 2D density plot</i>
-------------------	---

Description

geom_pointdensity() visualizes overlapping data points on a 2D coordinate system. It combines the benefits of [geom_point\(\)](#), [geom_density2d\(\)](#), and [geom_bin2d\(\)](#) by coloring individual points based on the density of neighboring points. This approach highlights the overall data distribution while preserving the visibility of individual outliers, making it ideal for data exploration.

Usage

```
geom_pointdensity(
  mapping = NULL,
  data = NULL,
  stat = "pointdensity",
  position = "identity",
  ...,

```

```

method = c("auto", "kde2d", "neighbors"),
method.args = list(),
adjust = 1,
na.rm = FALSE,
show.legend = NA,
inherit.aes = TRUE
)

```

Arguments

mapping	Set of aesthetic mappings created by aes() . If specified and <code>inherit.aes = TRUE</code> (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	<p>The data to be displayed in this layer. There are three options:</p> <p>If <code>NULL</code>, the default, the data is inherited from the plot data as specified in the call to ggplot().</p> <p>A <code>data.frame</code>, or other object, will override the plot data. All objects will be fortified to produce a data frame. See fortify() for which variables will be created.</p> <p>A function will be called with a single argument, the plot data. The return value must be a <code>data.frame</code>, and will be used as the layer data. A function can be created from a formula (e.g. <code>~ head(.x, 10)</code>).</p>
stat	<p>The statistical transformation to use on the data for this layer. When using a <code>geom_*()</code> function to construct a layer, the <code>stat</code> argument can be used to override the default coupling between geoms and stats. The <code>stat</code> argument accepts the following:</p> <ul style="list-style-type: none"> • A <code>Stat</code> ggproto subclass, for example <code>StatCount</code>. • A string naming the stat. To give the stat as a string, strip the function name of the <code>stat_</code> prefix. For example, to use <code>stat_count()</code>, give the stat as "count". • For more information and other ways to specify the stat, see the layer stat documentation.
position	<p>A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The <code>position</code> argument accepts the following:</p> <ul style="list-style-type: none"> • The result of calling a position function, such as <code>position_jitter()</code>. This method allows for passing extra arguments to the position. • A string naming the position adjustment. To give the position as a string, strip the function name of the <code>position_</code> prefix. For example, to use <code>position_jitter()</code>, give the position as "jitter". • For more information and other ways to specify the position, see the layer position documentation.
...	Other arguments passed on to layer() 's <code>params</code> argument. These arguments broadly fall into one of 4 categories below. Notably, further arguments to the <code>position</code> argument, or aesthetics that are required can <i>not</i> be passed through Unknown arguments that are not part of the 4 categories below are ignored.

- Static aesthetics that are not mapped to a scale, but are at a fixed value and apply to the layer as a whole. For example, `colour = "red"` or `linewidth = 3`. The geom's documentation has an **Aesthetics** section that lists the available options. The 'required' aesthetics cannot be passed on to the params. Please note that while passing unmapped aesthetics as vectors is technically possible, the order and required length is not guaranteed to be parallel to the input data.
- When constructing a layer using a `stat_*()` function, the `...` argument can be used to pass on parameters to the geom part of the layer. An example of this is `stat_density(geom = "area", outline.type = "both")`. The geom's documentation lists which parameters it can accept.
- Inversely, when constructing a layer using a `geom_*()` function, the `...` argument can be used to pass on parameters to the stat part of the layer. An example of this is `geom_area(stat = "density", adjust = 0.5)`. The stat's documentation lists which parameters it can accept.
- The `key_glyph` argument of `layer()` may also be passed on through `...`. This can be one of the functions described as [key glyphs](#), to change the display of the layer in the legend.

method	Density estimation method. Options are "auto", "neighbors", or "kde2d". <ul style="list-style-type: none"> • "auto" (default): Selects the appropriate method based on the number of points. "neighbors" is faster for small datasets, while "kde2d" is more efficient for large datasets. • "neighbors": Determines an appropriate radius and counts the number of points within this radius for each point. • "kde2d": Uses 2D kernel density estimation via <code>MASS::kde2d()</code>. Additional arguments can be provided through <code>method.args</code>.
method.args	List of additional arguments passed on to the density estimation function defined by method (e.g. <code>MASS::kde2d()</code>).
adjust	Multiplicative bandwidth adjustment for density estimation. A value less than 1 (e.g., <code>adjust = 0.1</code>) yields a smoother density estimate, while a value greater than 1 (e.g., <code>adjust = 5</code>) increases the level of visible detail.
na.rm	If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.
show.legend	logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display. To include legend keys for all levels, even when no data exists, use TRUE. If NA, all levels are shown in legend, but unobserved levels are omitted.
inherit.aes	If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. <code>annotation_borders()</code> .

Aesthetics

`geom_point()` understands the following aesthetics. Required aesthetics are displayed in bold and defaults are displayed for optional aesthetics:

- `x`
- `y`
- `alpha` → NA
- `colour` → via `theme()`
- `fill` → via `theme()`
- `group` → inferred
- `shape` → via `theme()`
- `size` → via `theme()`
- `stroke` → via `theme()`

The `fill` aesthetic only applies to shapes 21-25.

Learn more about setting these aesthetics in `vignette("ggplot2-specs")`.

  scale_color_viridis() +
  coord_cartesian(xlim = c(-1, 3), ylim = c(-5, 15))

```

stat_pointdensity

A cross between a scatter plot and a 2D density plot

Description

`geom_pointdensity()` visualizes overlapping data points on a 2D coordinate system. It combines the benefits of `geom_point()`, `geom_density2d()`, and `geom_bin2d()` by coloring individual points based on the density of neighboring points. This approach highlights the overall data distribution while preserving the visibility of individual outliers, making it ideal for data exploration.

Usage

```

stat_pointdensity(
  mapping = NULL,
  data = NULL,
  geom = "point",
  position = "identity",
  ...,
  adjust = 1,
  na.rm = FALSE,
  method = c("auto", "kde2d", "neighbors"),
  method.args = list(),
  show.legend = NA,
  inherit.aes = TRUE
)

```

Arguments

- | | |
|----------|--|
| mapping | Set of aesthetic mappings created by aes() . If specified and <code>inherit.aes = TRUE</code> (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping. |
| data | <p>The data to be displayed in this layer. There are three options:</p> <p>If <code>NULL</code>, the default, the data is inherited from the plot data as specified in the call to ggplot().</p> <p>A <code>data.frame</code>, or other object, will override the plot data. All objects will be fortified to produce a data frame. See fortify() for which variables will be created.</p> <p>A function will be called with a single argument, the plot data. The return value must be a <code>data.frame</code>, and will be used as the layer data. A function can be created from a formula (e.g. <code>~ head(.x, 10)</code>).</p> |
| geom | The geometric object to use to display the data for this layer, defaults to "point". |
| position | <p>A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The <code>position</code> argument accepts the following:</p> <ul style="list-style-type: none"> • The result of calling a position function, such as position_jitter(). This method allows for passing extra arguments to the position. • A string naming the position adjustment. To give the position as a string, strip the function name of the <code>position_</code> prefix. For example, to use position_jitter(), give the position as "jitter". • For more information and other ways to specify the position, see the layer position documentation. |
| ... | <p>Other arguments passed on to layer()'s <code>params</code> argument. These arguments broadly fall into one of 4 categories below.
